(54) Title: COMBINATION THIN-FILM STRESS AND THICKNESS MEASUREMENT DEVICE

(57) Abstract

A composite metrology tool, measures basic optical parameters of thin films (e.g., thickness, index of refraction, and birefringence) and stress (e.g., wafer displacements, such as bow and warp). These measurements are combined (e.g. in a processor) using optimization techniques to yield accurate overall information of the wafer parameters.

Technical Field

The present invention relates to measuring stress and thin film
parameters and, in particular, to a method and apparatus that combines initial
10 stress and thickness measurements and optimizes the calculations for both.

Background

There are a number of conventional metrology tools for measuring the
characteristics of thin films on semiconductor wafers. Typical parameters of
interest are the thickness (t), index of refraction (n), and extinction coefficient

(k). The conventional tools employ a variety of approaches for measuring these parameters, including spectrophotometry and ellipsometry. The most advanced and complex tools actually combine a number of these approaches to measure these parameters.

5 During the fabrication of wafers, thin films are deposited on the wafer. These thin films are typically formed from dielectric or metallic materials. The deposition process often produces residual stresses in the wafer. These stresses can affect the device manufacture and performance. Accordingly, there is an interest in measuring the stress after such a
10 deposition as a means of monitoring or controlling the manufacturing process.

 One way to measure stress is to measure the deflection (bow or warp) of the stressed wafer. Typically, one measures the wafer both before and after the stress-inducing manufacturing step. Knowing the wafer thickness, size, stiffness and thickness of the thin film, one can calculate the residual
15 stress from the change in shape. There is already at least one tool on the market which performs stress measurements in this way. Descriptions of this tool can be found in U.S. Patent Nos. 5,134,303 and 5,248,889, incorporated herein by reference.

 Briefly, devices of the type described in the above-cited patents
20 operate by directing a probe beam onto the surface of the wafer. A position sensitive photodetector is then used to measure the location of the reflected probe beam. During calibration, the central portion of the position sensitive photodetector is arranged to coincide with the location where the reflected probe beam would fall (based on Snell's Law) if the wafer surface was flat.
25 Any bow or tilt in the wafer surface will change the direction of the beam, causing a displacement of the reflected probe beam on the photodetector. The amount and direction of the displacement of the reflected probe beam on the detector provides a measure of the direction and extent of the bow or warp of the wafer.

30 As noted above, in order to determine the amount of stress based on the measurement of wafer warp, other parameters of the wafer, including

wafer size, stiffness and the thickness of the thin film must be known. In the prior systems, a value for thickness used in determining the stress value is selected based on the presumed or desired thickness of the film. However, if the thickness presumption is in error, the calculation of stress based on the measurement of the curvature of the wafer will be inaccurate.

Accordingly, it would be preferable to obtain an accurate measurement of the film thickness before calculating the stress levels in the film. Unfortunately, just as the stress calculation is dependent on the film thickness, conversely, the measurement of the thickness of the film is dependent on the level of stress in the film. For example, stresses in the film can directly affect the index of refraction of the material. While the coefficient of stress induced index change is typically small, the large stresses induced in films during the deposition process (approaching a billion Pascals) can lead to index changes as large as even a few tenths of a percent. If such changes occur and are not accounted for in analysis of the data on thin film measurement, relatively large errors will arise in the computation of thickness and extinction coefficients. As noted above, if the thickness of the film cannot be accurately determined, a determination of the stress cannot be accurately obtained since the level of measured warp can only be accurately converted into stress measurements if the thickness of the thin film is accurately known.

Another parameter which is of interest to semiconductor manufacturers is the birefringent effects of certain films. Many films, such as paralyne, have a natural birefringence. These films (as well as other films) also generate birefringence under stress. It is desired to have a system which distinguishes between the inherent birefringence and the birefringence effect due to stress in the films.

Summary

The subject invention which utilizes a composite metrology tool, which measures the basic parameters of thin films (e.g., t , n and k and

birefringence) and wafer displacements. These measurements are combined (e.g. in a processor) using optimization techniques to yield accurate overall information of the wafer parameters.

Brief Description of Figures

5 Fig. 1 illustrates a composite optical measurement system in which the present invention may be embodied.

 Fig. 2 illustrates a prior art method for determining the local tilt of a wafer.

10 Fig. 3 illustrates a method in accordance with the present invention whereby initial stress and thin film calculated values are combined using optimization techniques.

 Figs. 4a and 4b illustrate how to use a spherical mirror to determine a tilt detection system calibration factor.

15 Fig. 5a illustrates the tilt detection system calibration factors determined using the system of Figs. 4a and 4b, while Fig. 5b illustrates how using the calibration factor yields highly accurate tilt measurement results.

 Figs. 6a and 6b illustrate how to use a flat mirror to determine a stage tilt calibration factor.

20 Fig. 7 illustrates a method for supporting a wafer in a gravity-neutral manner.

 Fig. 8a illustrates the effect of supporting the wafer too close to the center; Fig. 8b illustrates the effect of supporting the wafer too close to the edge; and Fig. 8c illustrates how supporting the wafer 2/3 of the way from the center minimizes gravity-induced change in the shape of the wafer.

25 Fig. 9a illustrates stress measurements of three differently-stressed wafers supported on a conventional support, and Fig. 9b illustrates stress measurements on the same three differently-stressed wafers, supported in a gravity-neutral manner.

Detailed Description

In one embodiment, the subject system is implemented in a tool of the type described in published PCT application WO 99/02970 (published January 21, 1999 and claiming priority from U.S. patent application No. 09/015,839, filed January 29, 1998) entitled "AN APPARATUS FOR ANALYZING MULTI-LAYER THIN FILM STACKS ON SEMICONDUCTORS" and incorporated herein by reference in its entirety. As described therein, this tool includes multiple measurement systems, including a spectrophotometer, spectroscopic ellipsometer, as well as some multiple angle of incidence measurement devices. The outputs from each of the measurement modules are can be combined using appropriate algorithms to more accurately and less ambiguously analyze the thin film parameters. An embodiment of the tool described in published PCT application WO 99/02970 is shown in Fig. 1.

Briefly, the Fig. 1 apparatus is a composite optical measurement system 1 that which includes five different non-contact optical measurement devices and the reference ellipsometer 2 of the present invention. Composite optical measurement system 1 includes a Beam Profile Ellipsometer (BPE) 10, a Beam Profile Reflectometer (BPR) 12, a Broadband Reflective Spectrometer (BRS) 14, a Deep Ultra Violet Reflective Spectrometer (DUV) 16, and a Broadband Spectroscopic Ellipsometer (BSE) 18. These five optical measurement devices utilize as few as two optical sources: laser 20 and white light source 22. Laser 20 generates a probe beam 24, and white light source 22 generates probe beam 26 (which is collimated by lens 28 and directed along the same path as probe beam 24 by mirror 29). Laser 20 ideally is a solid state laser diode from Toshiba Corp. which emits a linearly polarized 3 mW beam at 673 nm. White light source 22 is ideally a deuterium-tungsten lamp that produces a 200 mW polychromatic beam that covers a spectrum of 200 nm to 800 nm. The probe beams 24/26 are reflected by mirror 30, and pass through mirror 42 to sample 4.

A fundamental difference between the apparatus described in WO 99/02970 and an embodiment of the present invention is the way in which

the processor 48 processes the data from the various measurement systems of the Fig. 1 apparatus. (In addition, as will be evident from the foregoing description, in its broadest form, the embodiment of the invention need not utilize all of the subsystems of the Fig. 1 apparatus.) That is, the present invention extends the concept described in published PCT application WO 99/02970 a step further by utilizing a determination of stress (in a preferred embodiment, from a measurement of angular displacement of the wafer) to optimize the calculations for both stress and thin film parameters (n , k and t).

An initial measurement of stress, through measurement of wafer tilt (bow or warp) can be obtained using the Fig. 1 system. More specifically, in order to maximize the accuracy of the ellipsometer portion of this device, it is important to know with precision the angle between the probe beam and the sample surface. Accordingly, the preferred embodiment is provided with a subsystem such as the stress measurement calibration systems disclosed in U.S. Patent Nos. 5,134,303 and 5,248,889 which measures the local tilt of the wafer.

Referring to Fig. 1 and as described in published PCT application WO 99/02970, the detector/camera 86 is positioned above the mirror 46 to view reflected beams off the sample 4 for alignment and focus purposes. As illustrated more particularly in Fig. 2, the calibration system directs a probe beam 103 via a beam splitter 104 (which is equivalent to the beam splitter 30 in Fig. 1) and lens 105 nominally normal to the surface 106 of the sample. Deviations in the position of the reflected beam 110, due to local sample tilt, are monitored using a position-sensitive photodetector 112 (such as a quad-cell photodetector) as the detector 86 in Fig. 1. Position-sensitive photodetectors are well-known in the art. See, e.g., U.S. Patent No. 5,134,303 referenced above. Referring still to Fig. 2, the amount "x" the reflected beam 110 is displaced on the photodetector 112 from the location 108 at which the reflected beam would hit the photodetector 112 in the absence of tilt of the sample surface 106 provides information about the tilt of the sample, which is usable to make fine corrections to the ellipsometer system.

Referring to Fig. 3, in accordance with an embodiment of the present invention, the local tilt information available from such a stress measurement system as shown in Fig. 2 is used to make an initial determination of stress in the thin film of the wafer. See block 202 of Fig. 3. For example, the amount and direction of the displacement of the probe beam on the detector provides a measure of the wafer surface local slope Θ . The wafer curvature $1/R$ may be derived from the first derivative of the slope

$$1/R = d\theta/dx, \quad (1)$$

The film stress σ can be determined from the curvature through the following relationship:

$$\sigma = [Et_s^2 / 6 (1 - \nu) t_f] (1/R) \quad (2)$$

where

t_s = wafer thickness

t_f = film thickness

E = Young's modulus of the wafer

ν = Poisson's ratio of the wafer.

The accuracy of the stress calculation highly depends on the accuracy of the calculated curvature value.

In order to obtain accurate calculations of the curvature, it is preferred to calibrate/correct the following:

- 1) the tilt detection;
- 2) the tilt variation introduced by the motion of the x-y stage carrying the wafer;
- 3) the nonflatness of the chuck surface if the wafer is supported by a chuck.

Referring to Figs. 4A and 4B, to accurately calibrate the tilt detection

system in one embodiment, a spherical mirror 402 made of a relatively large blank with a flat bottom is used. The focal length "f" of such a mirror 402 can be measured with a high degree of accuracy by using conventional approaches. For example, a collimated beam can be directed into the lens
 5 and the location of the focal point identified. The distance between the lens and the focal point gives the focal length of the lens. Once the focal length is known, then the radius of curvature R of the mirror can be determined with an equal accuracy since $R = 2f$.

By scanning this mirror 402 along x- or y-direction using the stage
 10 404, a linear relationship is obtained between the tilt sensor signal S_i and the scan distance d_i to determine the calibration figure k. For example, referring to Figs. 4A and 4B, and taking the x direction first, positions S_1 and S_2 on the photodetector 112 are determined for respective mirror/stage positions X_1 and X_2 . Then, the x-direction calibration factor k_x is calculated as

$$k_x = R \frac{S_2 - S_1}{X_2 - X_1}$$

15 a similar calculation is made for the y direction calibration factor k_y .

Due to the high quality of the spherical mirror (in one embodiment, surface quality $\lambda/4$, $\delta R < 1\%R$) and the high precision of the stage motion (in one embodiment, $\delta d < 5 \mu m$), the calibration factor k_i is precisely determined. The result of the calibration for one experiment is plotted in Fig.
 20 5a, while Figure 5b illustrates how an experimental accuracy was achieved within 0.1% (Residual = 0.99961) against an $R = 200$ mm mirror.

Referring to Figs. 6A and 6B, calibration of stage tilt variation in one embodiment is performed using a flat mirror whose dimension is comparable to the wafer. Given the flatness of the mirror in the range of $\lambda/4$, any tilt
 25 variation observed during an x- or y-scan is attributed only to the stage wobbling. In particular, as shown in Fig. 6A, the position of the beam incident to the photodetector 112 is determined for a first "x" position 502 of the stage 404. This position is treated as the "zero displacement". As shown

in Fig. 6B, the stage is then shifted in the "x" direction and the position 504 of the beam incident to the photodetector 112 is determined again. The distance between position 502 and position 504 is due to wobbling of the stage 404 and, thus, this displacement is subtracted from any sample tilt "x" direction measurements to compensate for the stage tilt that would otherwise "pollute" the sample tilt "x" direction measurements. A similar stage tilt calibration and compensation procedure is carried out for the "y" direction.

In addition to calibration as just discussed, improper support of the wafer can also impair measurement of wafer tilt, especially for the new, larger 300 mm diameter wafers. Particularly for such 300 mm wafers, gravitational deflection causes bending of the wafer under its own weight. This bending caused by gravity adds to the natural stress-induced bow (or subtracts from a stress-induced warp), introducing artifacts into the stress determination from wafer deflection. For more severely bowed wafers, setting the wafer on a flat chuck top for measurement tends to flatten the shape, reducing the curvature and thus resulting in an under-calculation of the stress. For weakly bowed wafers, the gravity will cause the wafer to conform to the chuck surface, which itself may not even be flat.

In accordance with an embodiment of the invention, the wafer is supported in a way such that the effects of gravity on wafer shape are minimized. As shown in Fig. 7, rather than place the wafer 302 on a flat chuck top, the wafer 302 is supported at three points 304a, 304b and 304c. By proper placement of the three support points, gravity-induced change in the shape of the wafer 302 is minimized, at least to first order. See Fig. 8c. If the support points are placed too close to the center of the wafer 302, the edge of the wafer 302 will tend to sag under its own weight. See Fig. 8a. If the support points are placed too far from the center of the wafer 302, the center of the wafer 302 will sag under its own weight. See Fig. 8b.

Calculation of the optimal location for the wafer support points is now discussed. From simple symmetry arguments, it can be inferred that the pins should be evenly distributed in circumference by 120°. The optimum radial

location comes from balancing the bending moments inside and outside the support radius. Assuming the wafer is a circular plate of uniform thickness, t , and density, ρ , then

$$M(r > r_0) = 2\pi\rho t \int_{r_0}^R (r - r_0) r dr$$

and

$$M(r < r_0) = 2\pi\rho t \int_0^{r_0} (r - r_0) r dr$$

5 The equilibrium condition requires $M(r > r_0) = M(r < r_0)$, which gives $r_0 = (2/3)R$. Other configurations may be possible as long as the support achieves the result of minimizing the effect of gravity inducing changes in curvature of the wafer during a measurement of the inherent curvature of the wafer. In this manner, more accurate measurements of stress can be obtained.

10 Figs. 9a and 9b illustrate the measured bow of three differently-stressed 300 mm wafers. The plots in Fig. 9a show measurements of wafer bow obtained for three wafers supported by a conventional support, while Fig. 9b shows measurements of wafer bow obtained for the same three wafers supported by a gravity-neutral wafer support. As can be seen from Fig. 9a, without the gravity neutral wafer support, the measurements for the three

15 differently-stressed wafers are nearly indistinguishable, while Fig. 9b shows the differences in wafer bow measurement obtained with the gravity-neutral wafer support.

20 The gravity-neutral wafer support has particular utility for large size wafers. Wafers that are 200 mm in diameter are far stiffer than 300 mm wafers as the diameter of 200 mm wafers is far smaller than that of 300 mm wafers, but the thickness of the 200 mm wafers is comparable. For 200 mm wafers which are moderately stressed, one could generally still distinguish

bow and warp even without the gravity-neutral support system, but the measured values would be slightly inaccurate.

It should be noted that the effects of gravity induced stress on silicon wafers is known in the art. (For example, see "Scaling Wafer Stresses and Thermal Processes to Large Wafers," Nilson and Griffiths, Thin Solid Films, V. 315, pages 286-293, 1998, incorporated herein by reference.) In this article, it is suggested that wafer supports be used to minimize gravity induced stresses in wafers during processing. In the present disclosure, similar wafer supports are proposed for use when measuring stresses in thin films so that the measurement will not be affected by stresses induced by gravity.

Turning again to Fig. 3, in addition to the step 202 for determining an initial stress measurement from probe beam displacement information, at step 204 information about local measurements of thin film parameters is determined using one or more of the various measurement modules described in the WO 99/02970 publication. As discussed, the tilt measurements are used to determine a likely level of stress in the film and the effect of that stress on the index of refraction and/or birefringence. The measurements from the thin film monitor modules (which can include the spectrophotometer, ellipsometer, and multiple angle of incidence devices) provide initial information about the parameters t , n , k and birefringence.

There are a number of possible approaches for combining the data at step 206. For example, once all the data is collected, the processor can use the data from the optical measurement modules to determine the characteristics of the thin film (i.e. thickness, index of refraction and extinction coefficient) in the conventional manner. Thereafter, the processor can calculate stress based on the bow and warp measurements. However, in this calculation, the "thickness" used in the stress calculation will be based on the calculated thickness, rather than on an assumed thickness. In this way, errors in the stress calculation which might arise if the thickness was simply assumed to be a known quantity can be minimized.

Alternatively, the processor can first use the bow and warp measurement module to determine the level of stress in the film. The results of this measurement can be supplied as a known parameter (i.e. level of birefringence) to the subsequent determination of the characteristics of the thin film based on the data obtained from the optical measurements. In this way, optical artifacts such a birefringence can be considered.

In a preferred embodiment, at step 206, all of the data is combined in a single algorithm which seeks the best fit of the data to both stress measurements and thin film parameters (t , k & n), such as an optimization algorithm. Such optimization routines utilize Fresnel equations in an iterative process (such as a least squares fitting routine) to provide an optimal solution for both stress and thin film parameters. One example of this type of optimization routine is described in "Multiparameter Measurements of Thin Films Using Beam-Profile Reflectivity," Fanton, et. al., Journal of Applied Physics, Vol. 73, No. 11, p.7035, 1993. Another example appears in "Simultaneous Measurement of Six Layers in a Silicon on Insulator Film Stack Using Spectrophotometry and Beam Profile Reflectometry," Leng, et. al., Journal of Applied Physics, Vol. 81, No. 8, page 3570, 1997.

The subject invention is not limited to the particular algorithm used to derive the characteristics of the thin film. In addition to the more conventional least square fitting routines, alternative approaches can be used. For example, the high level of computing power now available permits approaches to be utilized which include genetic algorithms. One example of the use of genetic algorithms to determine the thickness of thin film layers can be found in "Using Genetic Algorithms with Local Search for Thin Film Metrology," Land, et. al., Proceeding of the Seventh International Conference on Genetic Algorithms, July 19-23, page 537, 1997. These routines can be expanded to include a concurrent optimization of the determination of the level of stress in the thin film as well as the parameters t , n and k based on the multiple measurements.

The subject invention is not limited to the combination measurement

device described in WO 99/02970. Rather, the subject invention can be implemented in any combination device which calculates stress value (based on a measurement of wafer deformation or otherwise) and which also determines optical parameters such as t , n and k through optical measurements of a type that would be affected by stress. By combining measurements from both systems, a more accurate analysis of the sample can be obtained.

The combination of the optical measurement modules and a stress measurement module in a single tool, in addition to providing more accurate results, provides economic benefits as well. For example, a single tool has a smaller footprint and therefore takes up less space in the semiconductor fab. By combining technologies in a single tool, costs can be reduced by eliminating duplicate subsystems such as wafer handlers and computers. Furthermore, the combination can simplify and streamline decision making since the information from the two measurement modalities can be coordinated instead of producing conflicting results as in the prior art when two separate devices might be used. It should be noted, however, that while the preferred embodiment coordinates the data from the optical measurement module and the stress measurement module in the single tool, the invention is not so limited. Furthermore, in embodiments where the optical measurement data and the stress data are coordinated, the processor or other circuitry that coordinates the measurements may be "on-board" as shown in Fig. 1, the processor may be networked, or the processor may even be off-line.

What is claimed is:

1. A method of analyzing a wafer having a thin film thereon,
comprising:
obtaining at least one optical property measurement of the thin film
5 that is nominally indicative of the thickness of the thin film;
measuring a deformation of the thin film that is nominally indicative
of an amount of stress on the thin film; and
combining the at least one optical property measurement with the
deformation measurement to determine the thickness of the thin film and the
10 stress on the thin film.
2. The method of claim 2, wherein the combining step utilizes an
optimization algorithm.
3. The method of claim 1, wherein the step of measuring the
deformation of the thin film includes:
15 directing a probe beam to the thin film;
determining an angle between the probe beam and a reflection of the
probe beam from the thin film; and
determining the deformation based on the angle.
4. The method of claim 3, wherein the deformation determining step
20 includes accounting for a tilt detection system calibration factor.
5. The method of claim 4, wherein the wafer rests on a movable stage,
and wherein the tilt detection system calibration factor has been determined
by:
25 resting a spherical mirror on the stage in place of the wafer;
directing the probe beam to the spherical mirror;
moving the stage and, at a plurality of positions of the stage,
determining the angle between the probe beam and the reflection of the probe

beam; and

determining a relationship between the positions and the determined angles, whereby the relationship is the tilt detection system calibration factor.

5 6. The method of claim 3, wherein the wafer is resting on a stage, and wherein the deformation determining step includes accounting for a stage tilt calibration factor.

7. The method of claim 6, wherein the stage tilt calibration factor has been determined by:
resting a flat mirror on the stage in place of the wafer;
10 directing the probe beam to the flat mirror;
moving the stage and, at a plurality of positions of the stage,
determining the angle between the probe beam and the reflection of the probe beam; and
determining a relationship between the positions and the determined
15 angles, whereby the relationship is the stage tilt calibration factor.

8. The method of claim 3, wherein the step of determining the angle between the probe beam and the reflection of the probe beam includes:
directing the probe beam to be nominally normal to the thin film;
detecting a deviation of the probe beam after reflection from the thin
20 film; and
determining the angle based on the deviation.

9. The method of claim 8, wherein the step of detecting the position of the probe beam after reflection from the thin film includes determining relative intensities of the portions of the reflected probe beam on a plurality
25 of cells of a photodetector.

10. The method of claim 1, wherein the at least one optical property

measurement is obtained using at least one of a spectrophotometer, an ellipsometer and a multiple angle of incidence device.

11. The method of claim 1, wherein the combining step includes applying optimization routines used to solve Fresnel equations in an iterative process.
- 5 12. The method of claim 11, wherein the iterative process includes a least squares fitting routine.
13. The method of claim 1, wherein the combining step includes applying a genetic algorithm to concurrently optimize the determination of the stress as well as the thickness.
- 10 14. The method of claim 1, wherein the at least one optical property measurement is affected by the stress on the thin film.
- 15 15. The method of claim 1, wherein the result of the combining step also includes index of refraction and extinction coefficient.
16. The method of claim 1, wherein the method further comprises:
supporting the wafer only at points substantially two-thirds of the distance from the center of the wafer.
17. A method of analyzing the characteristics of a thin film on a semiconductor wafer comprising the steps of:
directing a first probe beam of radiation to reflect off the wafer
20 surface;
measuring the change in magnitude or polarization of the reflected probe beam induced by the interaction with the wafer and generating first signals responsive thereto;
directing a second probe beam of radiation to reflect of the

wafer;

measuring the angular deviation of the reflected probe induced by the interaction with the wafer and generating second signals responsive thereto;

5 analyzing the first and second signals in order to determine characteristics of the wafer including the thickness of the film and the stress in the film.

18. The method of claim 17, wherein the first probe beam and the second probe beam are generated by the same source.

10 19. The method of claim 17, wherein the analyzing step utilizes an optimization algorithm to combine the first and second signals.

20. The method of claim 17, wherein the angular deviation measuring step includes accounting for a tilt detection system calibration factor.

15 21. The method of claim 20, wherein the wafer rests on a movable stage, and wherein the tilt detection system calibration factor has been determined by:

resting a spherical mirror on the stage in place of the wafer;

directing a probe beam to the spherical mirror;

moving the stage and, at a plurality of positions of the stage,

20 determining the angle between the probe beam and the reflection of the probe beam; and

determining a relationship between the positions and the determined angles, whereby the relationship is the tilt detection system calibration factor.

25 22. The method of claim 17, wherein the wafer is resting on a stage, and wherein the angular deviation measuring step includes accounting for a stage tilt calibration factor.

23. The method of claim 22, wherein the stage tilt calibration factor has been determined by:
- resting a flat mirror on the stage in place of the wafer;
 - directing the probe beam to the flat mirror;
 - 5 moving the stage and, at a plurality of positions of the stage, determining the angle between the probe beam and the reflection of the probe beam; and
 - determining a relationship between the positions and the determined angles, whereby the relationship is the stage tilt calibration factor.
- 10 24. The method of claim 17, wherein the step of determining the angular deviation of the reflection of the second probe beam includes:
- directing the second probe beam to be nominally normal to the thin film;
 - detecting a deviation of the reflection of the second probe beam; and
 - 15 determining the angle based on the deviation.
25. The method of claim 24, wherein the step of detecting the position of the reflection of the second probe beam includes determining relative intensities of the portions of the reflected second probe beam on a plurality of cells of a photodetector.
- 20 26. The method of claim 18, wherein the analyzing step includes applying optimization routines used to solve Fresnel equations in an iterative process.
27. The method of claim 26, wherein the iterative process includes a least squares fitting routine.
- 25 28. The method of claim 17, wherein the analyzing step includes applying a genetic algorithm to concurrently optimize the determination of the stress as well as the thickness.

29. The method of claim 17, wherein the method further comprises:
initially supporting the wafer only at points substantially two-thirds of
the distance from the center of the wafer.

5 30. A method of measuring parameters of a substantially planar wafer,
comprising:
supporting the wafer only at points substantially two-thirds of the
distance from the center of the wafer;
directing a probe beam of radiation onto the wafer; and
determining at least one parameter based on an observation of the
10 interaction of the probe beam with the wafer.

31. The method of claim 29, wherein the points at which the wafer is
supported in the supporting step includes at least three points.

32. The method of claim 29, wherein the parameter determining step
includes:
15 determining an angle between the probe beam and a reflection of the
probe beam from the wafer; and
determining the deformation based on the determined angle, wherein
the determined parameter is the determined deformation.

20 33. The method of claim 29, wherein the parameter determining step
includes:
measuring the change in magnitude or polarization of the reflected
probe beam induced by the interaction with the wafer; and
determining optical properties of the wafer based on the measured
change in magnitude or polarization.

34. A method of calibrating a wafer tilt detection system for use in correcting a measured tilt of a wafer resting on a movable stage, comprising:
resting a spherical mirror on the stage in place of the wafer;
directing the probe beam to the spherical mirror;
5 moving the stage and, at a plurality of positions of the stage,
determining the angle between the probe beam and the reflection of the probe beam; and
determining a relationship between the positions and the determined angles, whereby the relationship is a tilt detection system calibration factor by
10 which an actual tilt measurement of the wafer may be adjusted.
35. The method of claim 34, wherein the relationship is a linear relationship.
36. The method of claim 34, wherein the spherical mirror has a surface quality characterized by $\lambda/4$ and $\delta R < 1\%R$) and wherein the stage motion is
15 characterized by $\delta d < 5 \mu m$), whereby the tilt detection system calibration factor may be precisely determined.
37. A method of determining a stage tilt calibration factor for use in correcting a measured tilt of a wafer resting on a movable stage, comprising:
resting a flat mirror on the stage in place of the wafer;
20 directing the probe beam to the flat mirror;
moving the stage and, at a plurality of positions of the stage,
determining the angle between the probe beam and the reflection of the probe beam; and
determining a relationship between the positions and the determined
25 angles, whereby the relationship is the stage tilt calibration factor.

38. An apparatus for analyzing a wafer having a thin film thereon, comprising:

a first light generator that directs a first probe beam of radiation to reflect off the wafer surface;

5 an analyzer that measures the change in magnitude or polarization of the reflected probe beam induced by the interaction with the wafer and generates first signals responsive thereto;

a second light generator that directs a second probe beam of radiation to reflect of the wafer;

10 a detector that detects the angular deviation of the reflected probe induced by the interaction with the wafer and generates second signals responsive thereto,

wherein the first light generator, the analyzer, the second light generator and the detector are provided in a single tool.

15 39. The wafer analyzing apparatus of claim 38, and further comprising:
a processor in the single tool programmed to analyze the first and second signals in order to determine characteristics of the wafer including the thickness of the film and the stress in the film.

20 40. The wafer analyzing apparatus of claim 38, and further comprising:
an interface via which the first and second signals may be provided to a processor in order to determine characteristics of the wafer including the thickness of the film and the stress in the film.

41. The wafer analyzing apparatus of claim 38, wherein the light generator and the second light generator are the same light generator.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 99/19873

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 G01B11/06 G01B11/16 G01B11/26

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 G01B H01L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

* Special categories of cited documents:

A document defining the general state of the art which is not considered to be of particular relevance

E earlier document but published on or after the international filing date

L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

O document referring to an oral disclosure, use, exhibition or other means

P document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

Z document member of the same patent family
